## Analyzing data on the level of cognitive processes

## Exercise 3 - Complex span task

In this exercise we will implement M3 models to experiments from Oberauer & Lewandowsky (2019) in which participants completed complex span tasks.

## Task 1: Basic M3 model

In task 1, we will implement the basic M3 model that can be applied to the complex span task. We will use the data set from experiment 1 from Oberauer & Lewandowsky (2019). You can find this data set in the bmm package under the name "oberauer\_lewandowsky\_2019\_e1".

In this experiment, 40 participants completed a complex span task. They were asked to memorize lists of 5 words in order which were interleaved by a distracting processing task. Participants were asked to read the presented words aloud. Participants reported the memorized words by selecting their responses from different displayed responses.

The experiment consisted of three different conditions regarding the distractors in the processing task that each participant completed. In the control condition, there were always new distractors ("new distractors") presented in the processing task. In the remaining conditions, the distractors in the processing task matched the words in the memory task. These distractors either matched the order in the memory task so that the same word was presented in the processing task as in the memory task ("old same") or the distractors were presented in a different order than the memory task words ("old reordered").

Here is an overview what the individual variable in the data set refer to:

- ID: participant ID
- cond: distractor condition in the processing task ("new distractors", "old same", or "old reordered")
- corr: number of correct responses (IIP)
- other: number of errors when a word from the list was reported, but at the incorrect position (IOP)
- npl: number of errors when a word *not* from the list was reported (NPL)
- dist: number of distractor words that were reported instead of a memory list word (only given in the "new distractors" condition)
- n corr: total number of correct responses in each trial
- n\_other: total number of IOP responses in each trial
- n dist: total number of distractors in each trial in the processing task
- n\_npl: total number of NPL in each trial

We are now interested in investigating the influence of the processing task on memorizing the words and how different cognitive processes were impacted, namely binding memory and item memory. Specifically, how well did participants remember the memory list words when the same word was displayed in the processing task ("old same") in comparison when it was not ("old reordered")?

To this end, we will implement the basic M3 model and will focus on the conditions "old reordered" and "old same". How are binding memory and item memory affected by the different distractor conditions? Does this match your expectations?

Task 2: Extended M3 model

In task 2, we will now extend our M3 model. In this model, we want to take the information about the errors that participants did regarding the distractors from the processing task into consideration. Therefore, we will use in this task the data set from experiment 2 from Oberauer & Lewandowsky (2019) in which the number of distractors in position (DIP) and distractors in other position (DOP) are reported as well. You can find this data set "data\_m3\_exp2" in the folder "data".

This data set includes some additional variables:

- condition: length of free time interval after each distractor, short (0.2 s; "Low") or long (1.7 s; "High") interval
- dip: number of errors when a distractor from the processing task was reported in the correct position as the memory item (DIP)
- dop: number of errors when a distractor from the processing task was reported, but from the incorrect position (DOP)

In this experiment, 27 participants completed a complex span task. Similarly to experiment 1, they memorized lists of 5 words in order while completing a not-to-be-memorized distracting processing task that immediately followed. Yet, in experiment 2, participants were asked to judge whether the presented word is smaller or larger than a soccer ball instead of reading the word aloud. This applied to the memory as well as the processing task. They again reported the memory words by selecting their response from a pool of displayed words.

The experiment consisted of two conditions regarding the free time interval after the processing task. The time interval after each distractor was either long ("High") or short ("Low").

In this task, we are interested in examining whether the free time interval ("High") or ("Low") after the distractors has an influence on the filtering of the distractors. Hence, we extend our M3 model for the complex

span task to estimate as well the filtering process apart from the strength of binding and item memory.

How is the filtering parameter affected by the different distractor conditions? Does binding and item memory differ among the free time conditions?
